Group-based healthy lifestyle workplace interventions for shift workers: a systematic review

by [Demou E](#), [MacLean A](#), [Cheripelli LJ](#), [Hunt K](#), [Gray CM](#)

A systematic review was undertaken to identify the existing evidence for group-based interventions delivered within workplaces to help shift workers lose weight, increase physical activity, improve healthy eating, or reduce sedentary time. Our findings offer decision support on organisational-level adaptations and intervention components for the delivery of group-based workplace interventions that promote healthy lifestyles for shift workers.

Group-based healthy lifestyle workplace interventions for shift workers: a systematic review

by Evangelia Demou, PhD,¹ Alice MacLean, PhD,¹ Lismy J Cheripelli, MSc,² Kate Hunt, PhD,^{1,3} Cindy M Gray, PhD²

Demou E, MacLean A, Cheripelli LJ, Hunt K, Gray CM. Group-based healthy lifestyle workplace interventions for shift workers: a systematic review. *Scand J Work Environ Health* – online first. doi:10.5271/sjweh.3763

Objective Shift work is a risk factor for many chronic diseases and has been associated with unhealthy lifestyle behaviors. Workplaces have great potential for promoting and supporting behavior change. We conducted a systematic review of group-based lifestyle workplace interventions for shift workers to (i) identify adaptations and intervention components that accommodate shift working and (ii) assess their impact on weight, physical activity, sedentary behavior and healthy eating.

Methods A systematic search was conducted in Scopus, Web of Knowledge, EBSCO and Ovid databases. Using pre-established criteria, independent pairs of researchers conducted the study selection, quality appraisal and data extraction.

Results In total, 22 studies on group-based workplace interventions for shift workers were included. Many demonstrated organizational level adaptations, such as flexible delivery times and paying employees' time for their involvement. Delivery locations near the workplace and management support were other key features. Common intervention components included competitive group activities, individualized goal setting, self-monitoring and feedback, staff involvement in intervention delivery, and incentives. There was moderate evidence for effectiveness on weight and physical activity outcomes, but insufficient evidence for healthy eating outcomes. No interventions focusing on sedentary behavior among shift workers were found.

Conclusion Current evidence demonstrates that group-based workplace interventions can be effective for supporting shift workers to lose weight and increase physical activity, while further research is needed to change healthy eating and sedentary behaviors. Our findings offer decision support on organizational-level adaptations and intervention components that are important to make interventions that promote healthy lifestyles more accessible to shift workers.

Key terms healthy eating; physical activity; sedentary behavior; shift work, weight.

Healthcare expenditure has risen continually over recent decades (1–5), and a significant proportion of these costs can be attributed to chronic health conditions such as diabetes, cardiovascular disease and asthma (6). Chronic diseases are the leading causes of death and disability worldwide and affect all socioeconomic groups. Poor lifestyles, including an unhealthy diet and physical inactivity, are associated with being overweight or obese as well as many chronic health conditions, reduced physical functioning, functional impairment and early exit from the labor market onto disability pensions

(6–8). These factors can hinder individuals' opportunities for extending their healthy working lives, and present employers with challenges such as higher sickness absence rates, reduced productivity, and premature loss of valued employees (9).

Unhealthy lifestyles are amenable to change, but achieving sustained behavioral change is difficult. Workplaces, as physical and social environments, have great potential for facilitating more positive lifestyle choices. Over 75% of working age people are in paid work and spend much of their waking time working (10).

Employers have legislative responsibilities for health and safety, and there is a strong business case for investing in appropriately-scaled initiatives to promote healthy lifestyles in the workplace, reduce employee turnover, increase productivity and employee engagement, and contribute to corporate social responsibility for the UK's ageing workforce (10, 11).

Workplace lifestyle interventions have been shown to improve employee health, increase productivity and be cost effective (6), and many are tailored to suit the specific operational and organizational requirements of different workforces (12–21). Group-based workplace interventions offer the advantage of peer support and cost-effectiveness, and are often the preferred option for healthy lifestyle initiatives in the workplace (22–24). There is evidence of the positive impact of workplace programs on health behaviors (25): increases in self-reported physical activity have been demonstrated, particularly in workplace interventions targeting physical activity (including walking) as opposed to general lifestyle change (26, 27). Workplace dietary interventions have also been shown to improve eating behaviors, for example increased fruit and vegetable intake and decreased fat intake (28). Other positive outcomes include: improvements in psychosocial health, quality of life and emotional well-being (29); and reduced presenteeism (29–31), absenteeism (31) and sickness absence (32).

Shift work and health risks

Recent reports highlight the ongoing discussion as to whether shift work should be classified as an occupational hazard (33). Shift work has been shown to be a risk factor for many chronic diseases (33–38), and links between shift work and weight gain, type-2 diabetes, coronary heart disease, stroke and cancer have been demonstrated (35). Shift work has also been associated with physical inactivity and poor diet (39). A recent study of the dietary characteristics of shift workers found that while diet quality does not differ between shift workers and those working regular hours, doing night shifts was associated with higher energy intake (36). Fujishiro et al (34) examined the cumulative exposure to rotating night shifts among more than 50 000 women from the Nurses' Health Study II, and demonstrated an independent contribution of night shift work to weight gain. The development of workplace lifestyle interventions specifically for shift workers is an emerging field (33). Such interventions require an approach that considers and accommodates not only the worker and operational characteristics, but also the organizational determinants that can act as barriers or enablers to successful implementation (33, 40). This study aims to identify the existing evidence for group-based interventions delivered within workplace settings to help shift

workers lose weight, increase physical activity, improve healthy eating, or reduce sedentary time.

Methods

Inclusion criteria

We included any studies and study protocols that described group-based interventions delivered in workplace settings, specifically targeting shift workers in the public or private sectors. Group-based interventions were defined as any interventions that delivered the intervention or specific components of the intervention to groups of employees rather than on an individual basis. For instance, this could include group educational seminars, team-based physical activity challenges and group physical activity training sessions to name a few. The intervention had to target at least one of the following: weight loss; physical activity; dietary improvement; and/or reduced sedentary behavior. The target population had to be aged 18–70 years. Outcomes of interest were weight, physical activity, diet, and/or sedentary time.

Exclusion criteria

Interventions delivered to the self-employed or employees working in small- to medium-sized enterprises were not included. Studies were excluded if there was no mention of shift work and/or interventions were delivered in a work setting that the research team agreed was not likely to involve shift working. Additionally, studies detailing interventions that were purely web-based were excluded from the review, as were studies with participants who had undergone weight loss surgery.

Search strategy

To devise our search strategy, the four main concepts relevant to the review were identified: (i) lifestyle; (ii) interventions; (iii) shift workers; and (iv) setting. A search term list was then developed for each concept, which included free-text terms and comprehensive controlled vocabulary items. We included both UK and US spellings and used truncation to capture plural and singular forms of words. We also used search techniques such as Boolean and proximity operators and phrase searching. We applied limits to year of publication from 2000 to the date of search (12th April 2018). The other limits applied were: human, adult and English language.

Our final search strategy was: [(Weight W/2 (Manage* OR Los* OR Reduc*)) OR ((Physical OR Exercis*)) AND (Capacity OR Perform* OR Train* OR Effort* OR Exert*)) OR (Healthy W/2 (Diet* OR Nutrit* OR Eat*

OR Food)) OR (Lifestyle)] AND [(Group AND (Program* OR Interven*))] AND [(Employee* OR Staff* OR Worker* OR Personnel* OR Workforce)) OR (Shift* W/2 Work*) AND ((Job OR Work) W/2 (Place* OR Site*))]. The search strategy was adapted to the specific requirement of each different database used.

To be as inclusive as possible, we consulted databases across the medical, public health, and social science disciplines: Scopus, Web of Knowledge, EBSCO (CINAHL, PsychInfo, Francis, and SocIndex), Ovid (EMBASE and Medline). All authors participated in screening the titles, abstracts and full papers using the inclusion criteria defined in the previous paragraphs. After excluding duplicates, a total of 5626 citations were obtained from the electronic search (figure 1). A further 298 citations were identified through hand-searching reference lists and the grey literature, leading to 5924 citations for screening. Each unique title was independently assessed by two reviewers, and where they did not agree, a third reviewer was consulted in order to reach a consensus.

After title screening, two reviewers independently reviewed 696 abstracts for eligibility. Of these, 281 publications were identified for full-text review. Two reviewers assessed all full texts, and a third reviewer independently read 10% for quality control. Any discrepancies were resolved by discussion. After full-text screening, 242 papers were excluded, and reasons for exclusion were noted. A further 17 papers were subsequently excluded as shift work was not specifically evidenced.

Data extraction

In order to develop the final data extraction table, members of the research team used a pilot version to independently extract data from a sub-sample (16%) of the included papers. The final version contained seven fields: first author and publication year; country; study design; workplace setting; study participants/sample size, intervention aim; and intervention description (including components).

Figure 1. Flow chart of the selection process of included studies

Quality assessment

Two reviewers independently assessed the methodological quality and sources of potential bias of all included studies using the Consolidated Standards of Reporting Trials (CONSORT) Statement (41) for randomized studies (25 items) and the Transparent Reporting of Evaluations with Nonrandomized Designs (TREND) Statement (42) (22 items) for non-randomized studies. Both quality assessment tools were used to systematically examine and appraise: title and abstract; scientific background and introduction; methods; results; and discussion. All items were rated as 1 when the condition was satisfied, 0.5 when it was partially satisfied and 0 if the condition was not met. The included studies were then classified as high, moderate or low quality if their final assessment score was >80%, 60–79%, and <60% of the maximum possible score (42), respectively. The two reviewers discussed any disagreements and, if necessary, resolved with reference to a third reviewer. Detail results of the quality assessment of all included studies can be found in the supplementary material (tables S1 and S2, www.sjweh.fi/show_abstract.php?abstract_id=3715).

Following quality assessment, three papers were rated as low-quality (43–45); these were included in the descriptive analyses, but excluded from the evidence synthesis (see below). Reasons for low quality included: lack of detail on the method used to generate the random allocation sequence or on the type of randomization; no information on the mechanism used to implement the random allocation sequence; and the absence of eligibility criteria for participants. Five study protocols were also excluded from the evidence synthesis. Seventeen studies of high or moderate methodological quality were included in the evidence synthesis (figure 1 and supplementary tables S1 and S2).

Analysis

To identify themes emerging from the review and key intervention components, a narrative synthesis approach was undertaken using three distinct steps: collating, summarizing, and reporting the results (46). The information was collated in tables, and the main findings summarized and reported by outcome of interest. This involved an iterative process, examining the evidence for intervention components that may have influenced the outcomes. Study protocols were included in this stage.

In order to assess the effectiveness of group-based workplace interventions, we performed an evidence synthesis based on the quality assessment rating and the significance or non-significance in relation to the outcomes of interest (weight, healthy eating, physical activity, sedentary behavior) and other relevant

outcomes (objective and self-reported health, sickness absence and other work-related outcomes). The criteria used for the evidence synthesis were: "strong evidence" – consistent results (in terms of statistical significance) between ≥ 2 high quality studies; "moderate evidence" – consistent results between ≥ 1 high quality and ≥ 1 intermediate quality study, or between ≥ 2 intermediate quality studies; "insufficient evidence" – identification of a single study or inconsistent results across studies; and "evidence of no association" – consistent results of a non-association in ≥ 2 studies (47, 48). Based on the definitions of Stennstra et al (48), a significant effect in one study and a non-significant effect in another were considered consistent findings, while a negative effect in one study and a positive effect in another were considered inconsistent findings.

Results

Characteristics of included studies

In total 22 studies were included in our review, and 17 of these in the evidence synthesis (figure 1). The main reasons for exclusion were: not a group-based intervention; not adapted for shift work; email, postal, purely web-based, environmental or individual (ie, one-to-one delivery) intervention; not a workplace setting; and target health behaviors and outcomes (eg, smoking, alcohol consumption) beyond the scope of this review.

The included studies were conducted over four continents (table 1), with 8 from North America [7 USA (44, 49–54), 1 Canada (43)], 8 from Europe [2 Denmark (55, 56), 1 UK (57), 1 Netherlands (58), 1 Finland (59), 2 Norway (60, 61), 1 Ireland (62, 63)], 5 from Australia (12, 45, 64–66) and 1 from South America [Brazil (67)]. There was a wide range of workplace settings including hospitals and care/nursing homes, manufacturing, fire and prison services, hospitality, casinos, transportation and other public and private sector organizations (table 1). The most common study design was the randomized controlled trial (RCT) (11 studies), followed by pre-post intervention (10 studies), and one study had a quasi-experimental design. The review includes 9725 participants in total [smallest study size: 33 participants (66), largest study size: 4536 participants (51)]. The majority of the included interventions had a focus on increasing physical activity (19/22; 86%) either alone or as part of broader interventions; 14 studies (64%) had a focus on improving diet (only 2 targeted diet alone), and 6/19 studies (32%) were holistic interventions with a primary focus on weight loss. Only 1 of the included studies reported sedentary behavior outcomes (self-reported) (45).

Table 1. Descriptive table of included studies. [RCT=randomized controlled trials; PA=physical activity.]

Study ID	Country	Design	Setting	Participants/ Sample size	Target outcomes	Intervention description
Morgan et al (64)	Australia	RCT	Aluminum smelter plant	Employees: Total N=110 Intervention: N=65 Control: N=45 Gender: Male 100% Age: 44.4±8.6yrs	Weight, PA, Diet	Intervention delivery Single face-to-face information session Intervention components A 3-month weight loss program consisting of: ▪ Information session: One face-to-face session (75 min): 60 min of education session ▪ Study website: 15 min technical orientation about the free weight loss website; weekly weight recording for 4 weeks, then fortnightly the next month, and for 1 week in the third month; 7 individualized feedback documents via email; supportive weekly email answers from researchers ▪ Resources: weight-loss handbook, website user guide, yamaxw200 pedometer ▪ Group-based financial incentives at two time points: An \$AU50 gift voucher per person for a local sporting equipment store for the groups with the highest mean percentage weight loss after 1 month and at program end
Strijk et al (58, 68)	The Netherlands	RCT and study protocol for Vital@Work RCT	Dutch academic hospital	Employees: Total N=730 Intervention: N=367 Control: N=363 Gender: Women (%) Intervention: 74.7% Control: 76.3% Age: Intervention: 52.5±4.8yrs Control: 52.3±4.9yrs	PA, Diet	Intervention delivery ▪ Intervention modified to fit within a common working day by choosing adequate time schedules for the provided yoga and guided workout group sessions ▪ Guided group sessions provided in two time blocks on all working days: 1) during lunchtime (3 sessions), and 2) after working hours (3 sessions) ▪ Guided group sessions conducted near the worksite (max. 5-10 min walk) Intervention components A 6-month lifestyle intervention consisting of: ▪ Personal Vitality Coach (PVC) visits: Three individual visits to a Personal Vitality Coach ▪ Vitality Exercise Program (VEP): Weekly guided yoga group session; weekly guided aerobic workout group session; weekly unsupervised aerobic exercise session (45 min at similar intensity as the guided workout sessions) ▪ Free fruit provision at group sessions
Pohjonen & Ranta (59)	Finland	RCT	The Social Services Department of the City of Helsinki.	Female home care aides (Total N=57) Intervention: N=50 Control: N=37 Age: 41.8±10.4yrs Sex (%)d	PA	Intervention delivery ▪ Physical exercise program conducted during work hours; within participants' own work units ▪ Facilities were near the worksite Intervention components A 9-month PA intervention consisting of: ▪ A 2 hour orientation and motivation session on physical fitness offered prior to exercise sessions ▪ Two lectures on leisure-time PA and effective exercise ▪ Supervised exercise (1-hr twice a week): Aerobics (games, aerobic dancing, step aerobics, and gymnastics), Muscular fitness ▪ Heart rate monitors used over entire shift ▪ Printed personal feedback and counselling

Continued

Intervention delivery

We found a range of delivery formats for workplace lifestyle group-based interventions for shift workers; from programs based around face-to-face information sessions (50, 64) or guided physical activity sessions (57, 60, 61, 68), to more composite programs that included educational lectures, supervised or structured PA sessions, guidance for individual PA activities and/or counselling sessions (12, 43–45, 49, 51–56, 59, 62, 63, 65–67). Some organizational level adaptations were identified as being important to make the interventions more accessible to shift workers. These included flexibility in timing of delivery (12, 43, 45, 53, 54, 60–63, 68), such as scheduling activities immediately before, after, and/or during shifts (51),

or ensuring that activities were offered at different times to cover employees on all shifts (45, 50, 62, 63). Other companies gave shift workers time off work for participation (53) or paid for employee time both to deliver (51) and participate (52) in the intervention. Another common measure was to ensure that physical activity sessions were held as near as possible to the workplace (52, 66). Management support (45, 50–53, 57) and encouragement (12, 50–52) for employees to join and continue to take part in the intervention were also used to support program delivery, and in two cases both management and shift working employees took part in co-production activities during intervention development (44, 45).

Continued

Intervention components

The interventions all included multiple components (table 1) often operating at different levels, including individual and environmental. A number of components featured in a large number of the interventions. These included competitive group activities (44, 45, 49, 51, 52, 57, 64–66), behavioral modification strategies such as individualized goal setting, motivation techniques, and feedback (12, 43, 45, 49, 51, 52, 54, 55, 57, 59, 64, 67), a leader or "go-to" person as a point of contact (43, 49, 51, 53, 57, 64, 67, 68), and incentives (eg, gift vouchers, coupons) (12, 49, 52, 53, 64–66). Peer support systems were included by utilizing peer champions (49), exemplar behavior from other staff or management (44), group leaders (51), and team competitions (45, 52, 64).

A wide range of resources were used to support intervention delivery including leaflets, fitness trackers,

personal trainer, dedicated webpages and counselling sessions (12, 43–45, 49, 51–55, 57, 59–68).

Components of interventions targeting weight

Interventions focusing on weight loss (43, 51, 53, 58, 64, 65) included group education sessions, sometimes combined with one-to-one information or counselling sessions or individualized support and feedback. A range of resources was used, including dedicated websites to complement workplace delivery, handbooks, pedometers, diet logbooks and healthy eating resources or supplies (eg, provision of free fruit). A strong emphasis was placed on the importance of group activities and peer support, and team competition was often included. Incentives in the form of financial prizes for teams (64, 65) or individuals (53) were also used. Environmental components included healthy options and portion sizes in the cafeteria (51).

Continued

Components of interventions targeting physical activity

The types of physical activity exercises offered were wide ranging (eg, aerobics, walking sessions, weight training, dancing, step challenges). The use of free resources, including pedometers/fitness trackers (49, 52, 53, 59, 61, 64–67), and feedback directly from an instructor, or via or printed material (43, 45, 49, 51, 52, 56, 59), was a key feature. The interventions often relied on team-based competitions to motivate employees to become more active (12, 44, 49, 52, 57). It was recognized that individualized components and tailoring for physical fitness levels were necessary for effective engagement (12, 43, 49, 52, 54, 55, 57, 59, 67).

Components of interventions targeting healthy eating

The components of interventions with a major focus on dietary improvement (45, 50–52, 62, 63, 65, 66) were often highly similar to the weight loss and physical activity interventions described above. These included free access to health clubs, personal training, food logs, cookbooks and healthy eating supplies (51, 52, 62, 63, 65, 66). Environmental changes included free coupons for healthy meals at the workplace cafeteria, changes in the price for healthy foods or the establishment of "healthy eating chat tables" at the cafeteria (52, 62, 63), and the provision of healthy options and smaller

portion sizes (45, 51, 62, 63). One of the interventions provided weekly educational classes delivered by a registered dietician (50), and incorporated an analysis of participants' health beliefs, nutrition knowledge and dietary behaviors prior to commencing the intervention (50), while another intervention combined both nutrition education sessions with environmental changes at the workplace cafeteria (62, 63).

Components of interventions targeting sedentary behavior

There were no studies focusing on changing sedentary behavior. However, one study targeting physical activity in truck drivers reported a change in the number of truck drivers sitting for >9 hours each day at work (self-reported) after implementing different interventions or combinations of interventions, including displaying healthy eating posters, supplying free fruit, promoting online resource, group educational sessions or step challenge (45).

Intervention effectiveness

Evidence synthesis on the effectiveness of the interventions on the reported primary outcomes (as well as other outcomes of interest, eg, health, sickness absence, work ability) was performed on the 17 studies rated as moderate or high quality following the quality assessment. Table 2 indicates that there is moderate evidence for improvements in weight and physical activity, and insufficient evidence for improvements in healthy eating (see also supplementary table S3, www.sjweh.fi/show_abstract.php?abstract_id=3715). Five of the nine studies reporting weight loss outcomes showed positive and significant impacts (52–54, 64, 67); three studies showed no significant difference between intervention and control groups (12, 49, 61, 62), one showed

inconsistent results between the intervention and the control arms (62), and one moderate quality study demonstrated a modest negative impact (57). Physical activity had four high or moderate quality studies reporting significant positive impacts (59, 64, 65, 67), three studies reporting a non-significant positive change or inconsistent results (49, 57, 68) and one study reporting positive self-reported change in physical activity levels without indicating if the change was significant or not (66). There were seven studies targeting healthy eating (49, 50, 62, 64–66, 68, 69), only two studies- one high and one moderate quality- reported significant positive impacts (66, 68), whereas five studies reported non-significant or inconsistent results (49, 50, 62–65).

All studies examined a range of health and wellbeing indicators, both objectively-measured (eg, blood pressure,

resting heart rate, body fat, fasting lipids, VO₂ max) and self-reported (eg, perceived health status, self-reported mental health, work ability). Objective and subjective health measures all had comparable numbers of studies reporting either significant positive impacts or non-significant, inconsistent or significant negative results (12, 49, 52, 56, 57, 59–61, 64–66, 68–71). Moderate evidence was available for improvement in some work outcomes: work ability (56, 68–71) and need-for-recovery (59). However, there was no evidence of any impact on sickness absence (56, 60, 69–71) (table 2, supplementary table S3). Heterogeneity meant that it was not possible to assess strength of effect, conduct a meta-analysis, or assess the effectiveness of specific intervention components on our target behaviors.

Discussion

Group-based workplace interventions to promote weight loss, physical activity and healthy eating behaviors in shift workers require a number of adaptations at the organizational level, including flexible delivery, proximity of intervention sites to the workplace, and management support and encouragement. The flexibility in delivery that was demonstrated reflected the complexity of intervening in workplaces via group-based interventions to improve shift workers' health behaviors and especially adapting to the specific challenges associated with differing work patterns. The interventions included in this review often targeted more than one of the outcomes of interest (sometimes with other outcomes) and had many components. Competitive group activities, behavioral modification strategies, such as individualized goal setting and feed-

back, and incentives were key components that featured widely. The results demonstrate moderate evidence of the effectiveness of group-based workplace interventions on weight and physical activity, but insufficient evidence for healthy eating. Moderate evidence was also demonstrated for health and work-related outcomes, but no significant impact on sickness absence was observed.

Research findings in context with previous studies

Previous research has shown that workplace interventions at the organizational level alone have modest effects on lifestyle behavior (72–74) and that the best evidence for effectiveness is from multi-component interventions that work across different levels (23, 74–77). This was also evident in the studies included in this review: many were multicomponent and included a number of adaptations to reflect shift working patterns and constraints in order to support, promote and implement the interventions. These adaptations and components ranged from changes to the cafeteria environment (45, 51, 62, 63), free resources and access to facilities (45, 49, 52, 53, 57, 59, 61, 64–66, 68), to flexible delivery in the workplace to ensure maximum reach (12, 43–45, 49, 50, 53, 54, 57, 60–63, 66–68).

Significantly positive impacts on diet have previously been observed in interventions delivered in the workplace during work-time, and those that involved staff in delivery and were multicomponent (78, 79).

Similarly, the interventions tailored for shift workers included in this review were all either delivered at the workplace, or very close by. Staff involvement was often demonstrated by having peer champions (49), staff or management role models (44), and group leaders (51). Examples of changes at an organizational level were evident in all interventions, including management involvement and support (12, 44, 45, 50–53, 57, 62, 63).

Another review on the general working population suggests that workplace health promotion can improve health outcomes and productivity (80). Goetzel et al’s (80) evidence synthesis on the impact of workplace health promotion interventions on health outcomes showed insufficient evidence overall but did include a number of individual studies demonstrating positive impacts. The studies included in our review demonstrate similar results for physical and mental health outcomes, with a number of studies demonstrating significant positive impacts (12, 49, 52, 54, 60). While we did not assess productivity per se, our review addressed productivity-related outcomes, including sickness absence and work ability (56, 59, 60, 69–71). Brox et al (60) demonstrated an increase in sickness absence in the intervention group, but a non-significant difference in self-certified sickness absence. While Jakobsen et al (56, 69–71) demonstrated a significant increase in self-reported sickness absence in the last year as measured by one item of the work ability index. Pohjonen et al (59) showed no change in work ability. Jakobsen et al (56,

69–71) reported a small to moderate significant effect in work ability, but no changes in other work ability measures (eg, work disability, influence at work).

Study strengths

A strength of this systematic review is that it included a comprehensive scrutiny of databases covering the medical, public health, and social science literatures. It also covers a large population (total N=9725), from ten countries and four continents. Additionally, it encompasses a breadth of workplaces, including hospitals and care/nursing homes, manufacturing, fire and prison services, hospitality, casinos, transport, and other public and private sectors, each with unique opportunities and often significant challenges for intervention development and delivery, and included sectors (eg, hospital, fire service, care home) which are recognized to have high levels of work-related health problems and sickness absence (81).

Study limitations

While the range of targeted behaviors and other reported outcomes, workplaces covered and intervention components included in this review is a strength, at the same time the heterogeneity of the included studies and intervention components do not allow for a meta-analysis, or assessment of the effectiveness of specific intervention components on our target behaviors. While the majority of identified studies were RCT, which are regarded as being methodologically robust, in the final evidence synthesis only seven RCT were included. Most of the studies were classified as moderate quality; only three (all RCT) were high quality. The pre/post design of a number of the studies makes it difficult to draw conclusions about causal relationships. Other limitations include the variability, validity and reliability of the reporting of shift work. As only papers that explicitly made some mention of shift work, however tangentially, were included in this review, it is possible that we could have inadvertently excluded other high quality studies, for example where interventions were aimed at an entire workforce, and not only shift workers.

Implications for policy and practice

Research into the development and implementation of interventions tailored specifically for shift workers is a new and evolving field with many evidence gaps. Papantoniou et al (33), highlight the increasing evidence that shift work increases the risk of major chronic diseases, draw attention to the large proportion of the current workforce exposed to shift work, and call for more workplace interventions addressing health-related outcomes among shift workers. A recent study on the

barriers and facilitators to a healthier lifestyle and the impact the working environment can have on shift workers found that the workplace environment was key in assisting shift workers to adopt and lead healthier lifestyles (82). Discussions are ongoing about whether to classify shift work as a workplace hazard qualifying for compensation (33). Denmark already considers breast cancer an occupational disease in shift workers, and compensates women with >20 years of night work who develop breast cancer (33).

Interventions for chronic disease risk reduction and prevention in shift workers require novel approaches to reflect the constraints of shift working. This review suggests a number of adaptations, including flexibility in timing of delivery (49–51, 53, 54, 56, 62, 63), allowing time off work for participation (53) and paying for employee time for intervention delivery and participation (51), that should be considered in developing future workplace healthy lifestyle interventions for shift workers. However, although there is some evidence in relation to weight loss and physical activity, more research is needed in order to maximize impact on lifestyle (including sedentary behavior), health and work-related outcomes.

Concluding remarks

Workplaces, as physical and social settings, have great potential for promoting health and wellbeing (6, 12–21, 82). Shift work has been associated with unhealthy lifestyle behaviors, which can contribute to increased risk for disease. Our findings suggest that workplace healthy lifestyle interventions with a group-based element can be implemented for shift workers by ensuring flexible delivery modes and organizational level adaptations, and can be effective in promoting weight loss and physical activity. This review can inform the development and implementation of future workplace interventions for shift workers to ensure that this specific workforce population can benefit from their workplace environments by promoting behaviors that protect against chronic diseases.

Funding

We would like to acknowledge the following funding sources: grant-funding from the Chief Scientist Office (CSO) (CZH-4-886) for work undertaken by CMG and LC, core funding from the CSO and UK Medical Research Council for AM and KH MC_UU_12017/12; SPHSU12), and a MRC Strategic Award for ED (MC_PC_13027). The authors declare no conflict of interest.
