Women's experiences of decision-making and informed choice about pregnancy and birth care: A systematic review and meta-synthesis of qualitative research

Abstract:

Background: The purpose of this systematic review was to describe and interpret the qualitative research on parent's decision-making and informed choice about their pregnancy and birth care. Given the growing evidence on the benefits of different models of maternity care and the prominence of informed choice in health policy, the review aimed to shed light on the research to date and what the findings indicate. Methods: a systematic search and screening of qualitative research concerning parents’ decision-making and informed choice experiences about pregnancy and birth care was conducted using PRISMA guidelines. A meta-synthesis approach was taken for the extraction and analysis of data and generation of the findings. Studies from 1990s onwards were included to reflect an era of policies promoting choice in maternity care in high-income countries.

Results: Thirty-seven original studies were included in the review. A multi-dimensional conceptual framework was developed, consisting of three analytical themes ('Uncertainty', 'Bodily autonomy and integrity' and 'Performing good motherhood') and three inter-linking actions ('Information gathering,' 'Aligning with a birth philosophy,' and 'Balancing aspects of a choice').

Conclusions: Despite the increasing research on decision-making, informed choice is not often a primary research aim, and its development in literature published since the 1990s was difficult to ascertain. The meta-synthesis suggests that decision-making is a dynamic and temporal process, in that it is made within a defined period and invokes both the past, whether this is personal, familial, social or historical, and the future. Our findings also highlighted the importance of embodiment in maternal health experiences, particularly when it comes to decision-making about care. Policymakers and practitioners alike should examine critically current choice frameworks to ascertain whether they truly allow for flexibility in decision-making. Health systems should embrace more fluid, personalised models of care to augment service users’ decision-making agency.
Dear Lauren McMillan,

Thank you for your response to our manuscript "Women's experiences of decision-making and informed choice about pregnancy and birth care: A systematic review and meta-synthesis of qualitative research" (PRCH-D-20-00158). Below, I have addressed each of the points from your response.

1. Figure 2 is cited in Section 'Synthesis findings', Page 11.

2. All references have been converted into Vancouver style, and the reference list (Pages 31-38) has been numbered accordingly. Table 4 (Pages 43-51) has also be revised to account for these amendments.

3. The PRISMA document has been removed.

4. Line numbers have been removed.

My apologies for the delayed response to these revisions. The initial communication went to my Junk Mail folder, instead of my Inbox. I hope this has not caused any inconvenience.

Best wishes,

Cassandra Yuill

Abstract

Background: The purpose of this systematic review (PROSPERO Ref: CRD42017053264) was to describe and interpret the qualitative research on parent’s decision-making and informed choice about their pregnancy and birth care. Given the growing evidence on the benefits of different models of maternity care and the prominence of informed choice in health policy, the review aimed to shed light on the research to date and what the findings indicate.

Methods: a systematic search and screening of qualitative research concerning parents’ decision-making and informed choice experiences about pregnancy and birth care was conducted using PRISMA guidelines. A meta-synthesis approach was taken for the extraction and analysis of data and generation of the findings. Studies from 1990s onwards were included to reflect an era of policies promoting choice in maternity care in high-income countries.

Results: Thirty-seven original studies were included in the review. A multi-dimensional conceptual framework was developed, consisting of three analytical themes (‘Uncertainty’, ‘Bodily autonomy and integrity’ and ‘Performing good motherhood’) and three inter-linking actions (‘Information gathering,’ ‘Aligning with a birth philosophy,’ and ‘Balancing aspects of a choice’).

Conclusions: Despite the increasing research on decision-making, informed choice is not often a primary research aim, and its development in literature published since the 1990s was difficult to ascertain. The meta-synthesis suggests that decision-making is a dynamic and temporal process, in that it is made within a defined period and invokes both the past, whether this is personal, familial, social or historical, and the future. Our findings also highlighted the importance of embodiment in maternal health experiences, particularly when it comes to decision-making about care. Policymakers and practitioners alike should examine critically current choice frameworks to ascertain whether they truly allow for flexibility in decision-making. Health systems should embrace more fluid, personalised models of care to augment service users’ decision-making agency.
Keywords

Pregnancy; childbirth; birthplace; metasynthesis; decision making, informed choice; qualitative; choice
Background

‘Choice’ has increasingly become a fundamental aspect of Western public health policy and practice, since the late 20th century. In United Kingdom’s (UK) National Health Service (NHS), for instance, informed choice is considered an ethical principle that guides ‘patient-centred care’. For maternity care, it is a buzzword that has engendered a growing body of literature around how to best facilitate decision-making and achieve informed choice among parents. However, promoting more service user autonomy and care experiences that are aligned with personal values can lead to complex trade-offs, as choices are based on more sophisticated, expanding services with less reliance on clinician’s intuitive judgment.[1] The issue remains that, while maternity care professionals believe they are offering choice, in reality, women still have a limited role in decision-making and do not feel their care is presented as a choice.[2,3] Some researchers have argued that informed choice, in particular, is, “at best, illusory”. [4,5] Presently, there are few systemic reviews related to it, or to women’s experiences of decision-making about pregnancy and birth care. We sought to address this gap and assess the qualitative research that has been undertaken to date.

Concepts of decision-making

Long-standing conceptualisations of decision-making and informed choice often assume that the decider uses a rational process to weigh up and decide between all available options.[6] This ‘rational process’ is connected to the tenets of classical decision theory, a concept that stretches across several disciplines, statistics, economics, neuroscience, physiology and psychology, and has been developed and discussed since the 1950s.[7] Classical decision theory is a collection of models of uncertainty, risk and utility that “prescribe the optimal choice of an option from an array of options, where optimality is defined by the underlying models and the choice is dictated by an explicit rule”.[8 p21]

The quality of human decision-making, in actuality, is frequently evaluated using the standards of classical decision theory; however, this has not rectified the persistent issue that human behaviour does not necessarily conform to these standards and cannot be adequately described by
them. Moreover, the long-held, assumed prescriptive and normative functions of the theory means that contemporary models of decision-making continue to inhabit these roles. The well-established health care model of ‘shared decision-making’ (SDM), “an approach where clinicians and patients share the best available evidence when faced with the task of making decisions, and where patients are supported to consider options, to achieve informed preferences” [9 p1361], is framed as an idealised process that flows from smooth interactions between health care professionals (HCPs) and service users.

The SDM approach aims for HCPs to facilitate service users’ movement from ‘initial preferences’ to ‘informed preferences’. Although the model steps away from clinicians making decisions outright for people, ‘preferences’ implies that service users are still not in full control of the ultimate care decisions or choice outcomes. The authors of the SDM model do acknowledge that it “is a simplification of a complex, dynamic process”, and as an educational tool for clinicians, it may prove effective; however, the extent to which it gives services users more power in the decision-making process is not well established, nor is there evidence of any association between SDM and service user health outcomes.[10,11]

Emerging models of maternity care

Outlining the assumptions underpinning decision-making and informed choice is important given the growing evidence of the benefits of different models of and options for maternity care in Western settings, and the prevailing notion of reproductive choice as a human right. Research demonstrating the positive clinical and social outcomes of midwifery-led continuity of care models [12], non-hospital birth settings [13-15] and reduced medical interventions [16] means there is an evidence base to underpin and strengthen the desirability of providing options. However, slow or stagnant uptake of new options among service users can be confounding, meaning policymakers and HCPs often rely on experiences of decision-making and choice to inform the best way to go about facilitating it. With the amalgamation of evidence concerning the clinical outcomes of different care options, it should follow...
that we also bring together the findings about women’s experiences of choosing these options.

However, to date, there are few systematic reviews of qualitative research on women’s experiences of decision-making and informed choice. Previous reviews have focused on decision-making in regards to antenatal screening [17] and delayed childbearing [18], what women value during childbirth [19] and how informal information sources influence birth decisions.[20]

In this review, against the changing maternity service landscape, we ask: what are women’s experiences of decision-making about pregnancy and birth care, and how is informed choice being addressed in this research to date? There are many definitions of informed choice; it is generally seen as a choice that is based on availability of relevant and balanced information. For the purposes of this review, we did not seek to provide a working definition of informed choice, as this forms part of our focus of enquiry. The review instead sought to include all studies with a stated focus on the issue, each of which could potentially define informed choice in a different way.

Methods

As the review encompassed published qualitative data, we employed a meta-synthesis approach to explore the relevant literature, which is anchored around “bringing together and breaking down of findings, examining them, discovering essential features and, in some way, combining phenomena into a transformed whole”. [21 p314] This new interpretation of, or ‘going beyond’ [22] research is one of the key aspects that sets a meta-synthesis apart from a meta-analysis, which aggregates findings to establish ‘truths’. The search and screening were conducted using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, an evidence-based framework used for reporting in systematic reviews [23,24], and was registered on the PROSPERO (Ref: CRD42017053264) database of protocols for systematic reviews.
Reflexivity

The review team was composed of four researchers who specialise in maternal and child health, maternity care and services and midwifery, and who conduct qualitative research on parents’ experience of maternity and birth care, primarily in the UK and Brazil. The first (CY) and second (CM) reviewers are medical anthropologists, and the third (HC) and fourth (NL) reviewers have backgrounds in midwifery, meaning we approached this review and meta-synthesis with an interdisciplinary lens.

Systematic search and screening

The initial search for articles was conducted on EBSCO (Academic Search Complete, CINAHL, Medline, SocIndex, PsycARTICLES), OVID (Embase, Global Health, Maternity and Infant Health Care) and Web of Science in January 2017. The grey literature was searched using OpenGrey and EThOs. A second search, which limited the results to articles published between 2017 and 2019, was run in August 2019 to check for new literature. Study content was not limited to a specific geographic region; however, articles had to be published in English. The searches focused on pregnancy and childbirth and did not include family planning, infertility, abortion or postnatal care as the focus was on choices about pregnancy and birth care. The search was filtered for studies employing qualitative or mixed methods research designs and analyses, which was key for the data extraction and synthesis process. Quantitative studies and quantitative findings from mixed methods studies, RCTs and open-ended questions from survey studies were excluded. The search strategy included Boolean phrases of “AND” and “OR”, and terms were generated using MESH headings, database thesaurus and free text. An example of the search strategy that was used on EBSCO is detailed in Table 1.

Articles were screened for fit with the inclusion criteria independently by two reviewers (CY and CM), first by title, then by abstract and following this by full text. In cases of uncertainty or disagreement, the third (HC) and fourth (NL) reviewers’ views were sought. Although potentially
relevant to a wider discussion, to maintain the focus of the review on decision-making and choice in
the context of more standard care pathways. Therefore, we excluded studies with a focus on a
specific risk factor or in relation to a specific intervention. Our search produced a good number of
papers about both VBAC and planned caesarean section. We felt that these had more of a specific
focus and decision-making contexts that warranted separate reviews in order to explore the themes
and unpack the complexities related to each. Table 2 defines the inclusion and exclusion criteria that
were used during screening.

Quality appraisal

Three reviewers (CY, CM and HC) independently carried out a quality assessment of the included
studies using a tool [25] for qualitative research that was adapted from Walsh and Downe.[26]
Initially, we intended to use CASP [27] for the qualitative research appraisal; however, this tool,
though popular, was found to be less sensitive to validity than other critical appraisal tools for
qualitative research.[28] We amended the tool by Rocca-Ihenacho during our quality appraisal,
decreasing the number of items on the checklist and adding in a more nuanced scoring system. The
resulting tool (Table 3) uses 33 items to appraise research on the basis of scope and purpose,
methodology, research design, sampling strategy, data collection and analysis, interpretation of data,
discussion of results, reflexivity and ethical considerations. Studies were scored from 0-2 for each
item to denote the quality of each item and were given an overall quality rating (0-22 = low; 23-44 =
moderate; 45-66 = high). In the few cases of uncertainty or disparity, the reviews outlined their
rationale for scoring and came to an agreement based on this discussion.

Data extraction and synthesis

The first reviewer (CY) extracted data from the selected studies to assess quality and to synthesise
reported results with supervision from the second reviewer (CM). No discrepancies were identified
during this process. The extracted qualitative data was coded line-by-line in NVivo to enable the
translations of concepts from one study to another and to build a qualitative synthesis, following

Thomas and Harden’s [22] methodology. This approach enables the synthesis to ‘go beyond’ in order
to identify key concepts in the studies and translate them into one another. The process of translation
allows the recognition of similar concepts used within studies, even if they are not explicitly stated as
such. The theories associated with these concepts are extracted so that a line of argument can be
developed and concordant concepts can be put together, bringing fresh interpretations.

Search results

The searches identified 2,198 records, and after screening both titles and abstracts, 88 were selected
for full text review. One article known to the authors was added, bringing the total to 89 records. Of
these, 47 were excluded for a number of reasons. The most common was because the study focused
on an aspect of women’s experiences outside of decision-making about pregnancy and birth care, or
there was little to no inclusion of decision-making or informed choice in the study aims or findings.
From the remaining records, five were removed because they were scored as low-quality during the
quality appraisal, leaving 37 records that were included in the meta-synthesis. Twenty-five were rated
moderate quality, and 12 were of high quality. A majority of the studies included in the final review
were peer-reviewed journal articles. One PhD dissertation [29] was included; however, the findings
extracted from the text were done with care so that the extended format did not dominate the
analysis or the emergent themes. The search results can be viewed in Figure 1.

Results

Descriptive findings

All of the studies reported in the review were conducted in nine countries, the UK (17), the US (7),
Canada (5), Australia (4), New Zealand (5), Finland (2), Denmark (1), the Netherlands (1) and Spain (1).
Several of the articles included in the review reported on studies that were conducted in multiple
countries, most notably Lagan et al [30], which was undertaken in five countries. The range of
countries included is small because the inclusion criteria was limited to research published in English,
and to studies conducted in countries with comparable medical systems to the UK. Table 4 provides a
summary overview of the included studies with their corresponding numbers.

While all of the research broadly focused on decision-making and informed choice, there was
a range of study topics, methods, sample sizes and analytical frameworks used to investigate the
aims. A majority of the research centred on place of birth.[29,31-54] Of these, 10 focused exclusively
on home birth [31,33-35,44,45,47,50,51] and one on free birth.[40] The next most common study
topics were decisions about birth [55-58] and influence of information sources.[30,59,60] Only two
studies [2,61] were concerned with informed choice as a primary study aim, and, finally, three studies
explored birth experiences [62], natural birth [63] and pain management.[64] Overall, place of birth
research was disproportionally represented in the studies identified.

There was a variety of study designs employed in the research under review. Most [29,31-
35,37-39,43,45,47,48,50,51,53-56,59,60,62-64] exclusively used interviews to collect data. Seven
studies [30,33,41,42,46,49,52] gathered data using focus groups, and the rest used a combination of
qualitative methods, usually interviews with either participant observation [44,57], non-participant
observation [2,61], narratives [40] or focus groups.[58] Sample sizes ranged from four to 135
participants, although one study [2] did not report their sample size. The average study size among
the records reviewed was approximately 32. Most of the studies [29-32,35-37,42-47,49,50,52-
55,59,62-64] used thematic analysis to generate results, while the remaining studies employed either
theory-guided analysis [38,40,47,51,56,60,61], qualitative content analysis [33,41], close textual
analysis [39,57] or consensual qualitative research analysis.[58] Two papers did not state their
analysis methods.[2,34]

The review included only two papers [32,47] that incorporated partners’ experiences of
choosing place of birth, and, of these two, one [32] focused exclusively on fathers. There are also few
ethnographic studies [44,57] of decision-making and informed choice in maternal health: most of the
articles we reviewed employed either grounded theory [34,38,45,48,50,60,61], phenomenological [31,40,51,56] or narrative [36,37,63] approaches as study designs. In general, the reporting of theoretical and methodological aspects of research was not as frequent as expected; for example, only 18 of the 37 studies reviewed stated their methodological frameworks. Because decision-making and informed choices are not straightforward processes and are enmeshed in wider socio-cultural relationships, it is important to situate the qualitative methodology within social theory. Moreover, we found little anthropological or sociological research on decision-making in maternal health, despite a rich body of work already established on reproductive and maternity experiences, both in the US and UK (see Davis-Floyd and Kitzinger).

Synthesis findings

Informed by women and their partners’ accounts of their decision-making experiences and the descriptive level of analysis, three overarching analytical themes emerged – ‘Uncertainty’, ‘Bodily autonomy and integrity’ and ‘Performing good motherhood’. These core themes are interwoven and overlapping as they reinforce and feed back into each other, and certain aspects of one can be confluent with those of another. There are three inter-linking actions – ‘Information gathering’, ‘Aligning with a birth philosophy’ and ‘Balancing aspects of a choice’ – as decision-making is an active albeit abstract process. The themes and inter-linking actions are framed by a ‘Temporal dimension’ that provides multidimensional depth to the process of decision-making and concept of informed choice. Figure 2 provides a visual conceptual map of the synthesis findings. All quotes in the following discussion are from the texts and participants of the original studies under review.

Inter-linking actions

Information gathering

This action illustrates the multiplicity of information-seeking and what women specifically gain from different sources. While women may seek information from sources outside of the medical sphere,
this does not mean that they do not rely on information from HCPs, who are still seen as valuable providers, particularly as active rather than static sources:

“I have had the pamphlets that the midwife gave me but I feel that if there were anything I really wanted to know then I would ring the midwife—my own midwife at the surgery...it’s just that you can have a conversation about it...in a book it’s just written there, whereas you can discuss it when you are with the midwife.”[61 p114]

Trust is a crucial strategy for navigating convoluted decisions, particularly trust in experts with the appropriate skills and knowledge.[65,66] As the participant above illustrated, the pamphlets from her midwife only provided so much, it was rather informal conversations that were more valued. Though HCPs are seen as trustworthy sources, women consistently reported looking for information, particularly for more detailed knowledge, outside of their appointments and beyond the ‘formal’ sources to family, friends and the Internet. These may provide a more comprehensive picture of care or specifics about different options, or be used to validate or confirm what HCPs have said:

Many wrote that they used the Internet to clarify information received from other sources—health professionals, family friends, or literature, such as pregnancy books and leaflets: “For me it was more to confirm what a doctor had said. Silly, I know, but I just wanted to understand it some more, which it helped me to do.”[30 p342]

Other sources of information can also be personal experiences, and care choices may stem from this internal history, particularly when women come to trust themselves and their bodies, which is common among those who chose to home or free birth:

“I knew that with my second, I was searching for a greater depth to the experience, something more intuitive as I had come to trust myself more than I had previously, not just through experience, but through research that supported my beliefs in understanding the science behind mammalian instinct, physiological birth and the huge value of the hormonal and emotional process.”[40 p7]

Information is a way to counteract uncertainty, whether it pertains to fear or safety, while simultaneously functioning as a space in which women perform good motherhood, gathering all the resources possible to demonstrate their knowledgeability and responsibility as a mother:
“I had a lot of fear around pain and what I considered to be this maiming experience of birth. I didn’t read anything for 9 months except birthing books, I swear. I mean, I just studied it. I knew it so well that the birthing classes suggested that I become a teacher. By the time I was in preparation for her birth, I had a lot of very, very positive expectations around the birth.” [38 p27]

The woman above has not only used intensive research to overcome her uncertainty and dread but has also been socially bestowed as an expert who is so knowledgeable that she can teach a birthing class herself. Information gathering can be used to shift an emotional outlook, whether it be for better or worse, relieving or inducing uncertainty, and it can also function as a strategy to forge or strengthen trust in sources of knowledge and in the self, by confirming what a HCP has advised or empowering the belief that birth can be positive, rather than “maiming”.

Balancing aspects of a choice

The next inter-linking action is concerned with looking at how women consider the different options available to them and, essentially, weigh the advantages and disadvantages of those they encounter. There are different everyday strategies that women use to navigate the many care decisions, including comparing information about an option or actively assessing and managing the uncertainty that is associated with their choice. ‘Balancing aspects of a choice’ focuses on the decision itself, how it is considered in relation to the self and the external world and how this shaped the ultimate choice outcome:

“I knew I had the information I was looking for generally after searching a number of sites and comparing a number of sources of information and when I felt satisfied I had learnt all that I could on a particular topic. I also liked to compare/discuss what I had found on the Internet with other sources, such as my midwife, obstetrician, GP, textbooks, etc.” [30 p341]

“I have heard, of course, of the possibility of giving birth in a birthing center, but I thought it was not appropriate for me, because I think that it suits women who are calm and confident better. Me, I have more of an anxious
nature. As I reflected during the course of my pregnancy, I came to the conclusion ... I am too able to imagine all
the problems that could occur. It makes me feel safe to be in a hospital."[55 p163]

Balancing involves understanding and managing uncertainty, developing “safety nets” in the event of
a complication during labour and childbirth. This phenomenon is not a recent one. McClain [67,68]
found that women’s choices of birth services were based on balancing the risks and benefits of each
option. Risk and benefit have thus remained strong vectors along which decisions are made against
others; the central question being: what is the risk to my body and my baby?

“We just won’t let labour go on that long – if things aren’t progressing, we’ll ask for a caesarean section...I’ve done
everything I can to be fit and healthy. I’ve done NCT [National Childbirth Trust] – very helpful apart from they’re a
bit mad, and you have to take it with a pinch of salt. They are very pro- ‘active birth’ and anti-drug.”[36 p61]

“So once I got past the anxiety issues, and making that final decision, and knowing that if I didn’t want to go ahead
with it then I could always back out and still go to the hospital.”[35 p125]

Women pursuing non-hospital births reported assessing and managing uncertainty regularly
throughout their pregnancy, revealing the extent to which uncertainty is embodied and how bodily
parameters orient decisions. Balancing the aspects of ‘alternative’ maternal care choices acquire
legitimacy and potency as medical tests and clinical appointments confirm a ‘low-risk’ status, and
optimal fitness, by these standards, is affirmed. So powerful are these biomedical definitions of health
and risk that they determine pathways of care, even if it is generally outside its bounds and setting:

“I didn’t actually decide to have a homebirth until I had had my 28-week gestational diabetes test, because I had
had a false positive with that, so then after I’d had my second test for that then I decided that yes, I wanted to go
ahead and have a homebirth. I needed to have everything clear in my head that everything was going to be
healthy for me to be able to have a homebirth.”[35 p125]

Through this action, we can see how blended decision-making can be: it must encompass both
physiological and social considerations, reflecting the dynamic nature of childbirth knowledge itself,
which is comprised of biological processes and social praxis.[69] Balancing is an effective strategy for
navigating these complex decisions and myriad information sources pertaining to them.

Aligning with a birth philosophy

In terms of decision-making, an important part of the process is aligning with a specific ‘birth
philosophy’, or perspectives that inform the ways in which people understand the world and life in it,
further shaping the information women access, the care opinions they ultimately choose and the
ways they justify their choices. Birth philosophies, as they are presented in the literature reviewed,
fall primarily into two camps; one views pregnancy and birth as ‘medical’ events, while the other sees
each as ‘natural’ events. Many women’s perspectives reflect the medicalisation of childbirth in
Western countries and as a result, they entrust their bodies, which can viewed as sites of danger, to
medical care:

“I had a couple of people going ‘oh but it’s all just a natural process and it’s all good and you should be all fine’;
well actually if you look around the world most of the women die in childbirth, that’s the riskiest thing women do; I
wasn’t terribly impressed with that argument.”[41 p10]

“I mean, it’s a medical thing. I’m not going to stay home if my appendix bursts either. I want the people who are
trained and know what they’re doing to deliver my baby. Why wouldn’t you go to the hospital? That’s crazy!”[57
p712]

Through this lens, placing one’s self anywhere but in a hospital and into medical care is “crazy”;
however, women who see pregnancy as a natural event view ‘alternative’ options as opportunities to
maintain their physical agency. These women often evoke the histories of women who have given
birth outside of the hospital and the desire not to interfere with their bodies’ physiological processes.
They do not conceive of their bodies as sites of danger, rather as those undergoing an organic event,
and that care should indicate this:
“For me, pregnancy is a totally natural thing. If one is in good shape, in good health, there is no reason why one should go to the hospital to have access to medical help. Yes, things can go wrong, and this is why it reassured me to know that midwives are paired up with the hospital ... But if things go well, I have no reason to ask for a doctor’s help.” [59 p163]

“I think [TMH]- it’s a hospital, which if you are sick or if you’ve had an accident, that’s great, that’s exactly what you want; but I wasn’t sick, I was having a baby – it’s a perfectly natural process that millions of women all around the world have managed to do without nice shiny hospitals” [42 p600]

The insinuation that giving birth outside of the hospital is right for – if not, limited to – women who are in “good shape” and “good health” reveals the overwhelming burden of risk discourse in maternal health. Despite this crossover between the ideological camps, there were indications in this review of emerging perspectives that allow each to dovetail, but increasingly underscore the importance of individualised choice as a way to display and promote appropriate motherhood and maternal care:

“For me a birth is natural when I can keep the child close to me and do what I feel right in the process, whether I will use technologies or I won’t. First and foremost the natural in birth means my choice and my decisions. If I feel that an intervention is necessary it is not against the idea of a natural birth, nor is the use of medicine.” [59 p163]

Engaging with, forming and embracing a birth philosophy are all important steps along the decision-making process and contribute to a woman’s ability to make an informed choice about her care; however, it is essential that these ‘ideologies’ or ‘philosophies’ are critically examined. Each ideology contains slippages, and their co-existence can still be regarded as contentious, yet they are repeatedly spoken of in decision-making about maternity care and remain integral to this process.
Analytical themes

Uncertainty

‘Uncertainty’, along with the following two analytical themes, encompasses several different experiences that are related to mothers’ concerns about the unknown and the course of pregnancy, childbirth and maternity care, all of which shape women’s decision-making and the options they ultimately pursue. Uncertainty about the unknowns of pregnancy and childbirth is most prominent among first-time mothers, who do not have previous experience to inform their choices and may approach care with a level of wariness:

“You don’t know how painful it is going to be, it’s the fear of the unexpected.” [64 p3]

“The birthing center, I knew it existed, but I didn’t really know. But for a first baby I felt safer at the hospital, because they have all the technology, and if there are problems ... I am already at the right place. So, the fear of the unknown, I’d rather be in a place where I know that everything is readily available.” [59 p163]

Anxiety about having a straightforward pregnancy and birth, fear of pain, and lack of experiential knowledge contribute to women opting for what is viewed to be the safest pathway of care, using what is perceivably less risky to guide their decisions. Uncertainty, which encompasses risk, safety and fear, was frequently cited as an influence on decision-making, regardless of parity. Fear, such as fear of pain, can be a powerful motivator for choosing a specific place of birth:

“Well, of course I am gonna go in and have an epidural, because that’s what the hospital is there for. And of course I am going to take whatever is – I don’t want to handle pain, I’m scared of pain, so I’m definitely going to do it the easy way.” [55 p644]

Fear of pain is not the only anxiety that mothers experience; some women expressed uncertainty about the safety of the hospital environment, which directed their pregnancy and birth care decisions. Safety and risk are constructed in several different ways in these cases. For some, medical
technology, interventions and environments connote safety, security and quality care, while for other, these are view as inherently risky, down to the microscopic level of “germs”:

“You come out of the hospital and you feel like you are covered in germs and you just wanna have a shower and change your clothes so why would I wanna take a newborn who doesn’t have any kind of antibodies in their system yet into a hospital? It didn’t make logical sense to me.”[45 p579]

“That CTG or that doptone is also based on fear. Yes, then you trust the machine more than what I tell you about how it’s going, or your own intuition. And I understand that you think, as a midwife, you don’t want to be sued, and you don’t want a dead child, and you feel responsible. I understand all that. But it takes away my control over my delivery and my body and what I want.”[55 p7]

“So, I went on a hospital tour and I said to myself ‘I don’t feel safe here,’ anyone can come in and out and I’m not in control.”[44 p270]

Fear, risk and safety appear to be part and parcel of uncertainty. Fear about childbirth is strongly connected to the unknown, whether it concerns pain levels, interventions or entire approaches to maternity care, as opposed to concrete calculations of risk, displaying how uncertainty is remains enmeshed with ‘being in control’.

Bodily autonomy and integrity

Control, and how it is linked to choice, is a topic widely covered in reproductive and maternal health research. Women frequently discuss their maternity experiences in terms of control, whether it be losing it, maintaining it or reclaiming it. We chose to shift the perspective to bodily autonomy and integrity because ‘control’ is not always explicitly stated by participants, and experiences often refer back to the body. This theme, as with the others, is multifaceted, encompassing a range of experiences. First, the denial of bodily autonomy is commonly coded as “loss of control” by researchers:
“[Y]ou can be in whatever position you want, you can have whatever doctor you want, but then the nurses come in and they tell you to do this, so you do it” (Shirley). Andrea also noted, ‘During prenatal classes, they had shown us some labor positions to try and stuff, but [in hospital] they were like, ‘Oh, just try and rest. Lie down.’”[55 p645]

“I felt violated and humiliated. It ended up with the doctor telling me my baby was stuck and she would try to pull my baby out, in theatre, with an epidural, surrounded by strangers, in case it didn't work in which case they would perform an emergency c-section. It was the most awful experience of my life.”[40 p5]

Experiences in this category may be quite subtle, such as threats of induction or discussions that aim to limit women’s decisions about their bodies and care, to more transparent, like being forced to lie down, too traumatic, in which women are left feeling “violated”. During these experiences, women’s control over their care is restricted or removed completely, and this is embodied through the type of care received and the way it is received. Some women seek to protect this autonomy and integrity through their care decisions:

“...you’ve got control over your environment, you can decide what position you’re in, whether you need something to eat or a bath or a scented candle or, you know, you might want none of those things, you might have time for none of those things... And being somewhere that is familiar and safe and happy and that is not intruded on by other people and their various dramas, positive or negative. And where you can control the cleanliness and the food and anything else, and you can go to your own bed afterwards and ... yes. It just feels to me some ... more comfortable.”[36 p62]

“When I contacted the midwife, I had not decided for a home birth yet, I contacted her because I wanted to have a respectful birth, without epidural analgesia, and I wanted a person who respected that. I knew that I was not going to find a healthcare professional who respected me in this way [at the hospital]...”[51 p19]

The review outcomes, which included 10 studies of home births and one of free birth, suggest that birthing outside of the hospital is a common route women take if they are concerned with control over their bodies and agency in their care. Pursuing home birth, in which limited medicalisation is
ideal, can be viewed as a choice that is informed by and reflects women’s desires for autonomy and integrity, and those who choose this type of care often centre their motivations around their bodies.

Performing good motherhood

The final analytical theme is ‘performing good motherhood’ and is related to responsibility and risk, which are often ascribed to mothers to manage.[36] This theme revealed a pervasive, gendered cultural norm that ‘good’ motherhood and birth takes place in a hospital with a team of medical professionals. It may be one of the reasons why women planning home births often describe thorough information gathering and risk assessments, and speak about negotiating their care within the purview of biomedicine:

She [participant] used biomedical knowledge to support her view that birth can safely be conducted at home when risks have been excluded by prenatal care. For this purpose she and her husband had searched medical databases to find research on home births. To secure her own low-risk status she had extra examinations done during her pregnancy. She organised her home birth to represent conditions in the hospital as far as she could.[47 p1117]

Re-creating the home to mimic a hospital reinforces the authoritative position of the medical system and the norm that maternity optimally takes place within it, while simultaneously demonstrating this woman’s responsibility as a mother, despite her decision to birth outside of this system. However, opting for hospital-based and more medicalised care remains the ultimate act of risk management, and, for women choosing these, risk may be spoken of in terms of danger and death, each seen as possibilities in the spaces outside of it:

“I said, ‘Look, don’t worry, I’m not going anywhere there’s no doctors.’ And he [GP] said, ‘Yes, I’m just saying, you know, because you know the chances are ... It’s a 40 minute journey [referring to transfer to OU during labour]. Do you want to risk that?’ No! [Laughs] But yeah, that’s all he really said, but he was right...I’m not risking that, I’m not risking the baby’s life or my life.”[36 p58]

“Why would I want to put my baby in danger? What if something went wrong?”[57 p712]
Within biomedicine and wider social discourses, pregnancy is constructed as a time of risk and its reduction [70], and childbirth, subsequently, an event that requires not only hospitalisation but also one that acquires a moral subtext, making it difficult for parents choosing different care to escape blame and stigmatisation [71], and adding a ‘burden’ of choice onto women:

I made an early decision to go to hospital to give birth, even though my midwives here were extremely experienced. And I did talk through that with [my midwife] and say that possibly I might decide not to go to the hospital if everything started very quickly... Yes and I wanted that to happen and for the decision to be taken away from me. I craved a home birth, but ‘my niggles of fear’ wouldn’t let me take the risk. An alarm bell goes off in the back of my head that says but what if something happens? ...(And my midwife said that if you have it in your head (that you don’t feel safe) then it is going to get in the way of the labour taking place and that you need to be in the place where you are going to birth and then it will just happen.[53 p52]

Coxon and colleagues [36] argue that discourses of responsibility continue to constrain women’s decisions and the way they discuss birth options outside of the norm, and many of women’s reported decision-making experiences uphold this idea.

Temporal dimension of decision-making and informed choice

There are several levels in which temporality underpins decision-making and informed choices about maternity care during pregnancy and for birth. On the most immediate level rests a continuum from ‘early pregnancy’ to ‘late pregnancy’, during which options are considered, information gathered and decisions are made. There is not necessarily a pattern of when decisions about maternity care are made along this continuum, and there may not be specific decisions points along it, but rather decisions can build or shift over time. On the other hand, significant influences, such as attending a friend’s home birth early in pregnancy, can provide a more concrete time stamp for a decision shift along this continuum:
“I had a powerful experience when I was early on [in my pregnancy]. It was home birth of my friend’s...I think for me, deciding to go with home birth had somewhat to do with being there at a home birth...That seems worthwhile: I want to be a part of that. I want that. And so early on, we made that decision.” [58 p175]

“[F]rom the beginning I knew [hospital birth] was the course of events” [43 p47]

“Just wanted to leave the window open, because I liked the idea of doing it but I wasn’t completely ready to make that decision, and I think as I got further along in my pregnancy, it was easier for me to make that decision.” [35 p125]

The next level within this temporal dimension of decision-making is constituted from past personal experiences, which encompass before pregnancy, previous birth(s), significant life events and family experiences of the recent past. Like the themes of maintaining bodily integrity, managing uncertainty, and performing good motherhood, it also has the potential to be a highly emotional layer, where memories of trauma or loss reside and shape how decision-making is approached and which care options women and their partners take seriously:

“I don’t want it to go like it went last time. I had quite a traumatic first birth and I had basically a series of events happened and I felt that I had lost control and I hadn’t been informed properly when I was in labour. So, things kind of went out of control. This time round I’m, I’m planning to be at home because that gives me an element of control that I didn’t feel that I had when I was in hospital.” [64 p6]

“My brother had ... well his wife had a baby at home and the baby died ... and I think that affects ... that sort of affects the family for a long time, you know, anyone in the family who was involved with that or remembers that, you can’t, [home birth is] just a no-no for us.” [36 p59]

The deepest layer of this temporal dimension of decision-making is the historic past, which often is embedded within women’s perspectives of birth and their decision-making processes. The ‘past’ or ‘old days’ are often used to justify a decision, particularly when it comes to place of birth. This
justification occurs along two lines: either it is connected with traditional birthing practices, inherent biological drives or mammalian physiology to strengthen the choice to home or free birth, or it is connected with historical maternal and infant mortality rates to make a case for hospital birth:

“I accepted that like any other mammal, I can give birth so the implicit trust I have in my biology played a fundamental role in this acceptance of birthing alone.”[40 p8]

“I just know that bad things can happen, like to the baby’s blood or heartbeat or whatever. Birth is really dangerous and women used to die all the time before hospitals, and I guess they still do in poor countries and all that.”[57 p712]

In conceptualising temporality, it is easy to present it linearly, reflecting how individuals move forward in time, which is not necessarily the case for a cognitive process like decision-making. Instead, women may shift between or draw from different temporal modes when they working through and making a decision.

Discussion

Though all of the studies we review concerned decision-making and choice, few focused primarily on the process of decision-making, as opposed to the influences on it or placed informed choice as a primary research aim. This could be attributed to the artefact of the research methods used, but this limited focus means that clarifying maternal health decision-making is tenuous at times and tracing the development of informed choice in literature published since 1990 is difficult. In their analyses, many of the review sources failed to surface deeper themes within this vein, leaving questions about what we are missing when we talk about women’s decision-making in relation to birth, for instance how social and institutional power might come to be embodied through decisions about care.

Ultimately, we found that decision-making is not only dynamic but also a temporal process, in that it is made within a defined period and invokes the past, whether this is personal, familial, social or...
historical. However, few of the papers reviewed explicitly explored timing of decisions; instead, time was discussed within reported influences on choice.

Different decision-making strategies intersect over the course of pregnancy, how information is collected and scrutinised and how options are weighed within different boundaries. Feelings of satisfaction, anxiety and safety are used as an inner guide for making a decision, demonstrating the extent to which emotional and bodily well-being are considered when choosing significant care options, such as birth setting. Triangulating information about pregnancy and care is common, given the scope of resources available; however, the act of confirming suggests that relationships of trust can still be difficult to manage with the overwhelming sense of risk attached to maternal health.

Within motherhood, there can be a multitude of experiences, narratives and identities that, like information seeking and relationships with choice, are constantly unfolding and in flux, within a dynamic decision-making field of maternity history, uncertainty, birth ideology and care options. Aligning with a birth philosophy, whether consciously or not, is a crucial component of decision making. Generally, birth philosophy is pushed, by researchers and parents alike, into two fundamental camps, in which pregnancy and birth are treated either as a medical event or a natural event. This dichotomy is consistently generated and reproduced within pregnancy and birth discourse, rhetoric and research, reinforcing a binary tendency in analysis that does not realistically reflect the ways women consider maternity. The ‘natural event’ ideology features predominantly in this review because nearly a third of the included studies focused on home birth or free birth exclusively, and this may not be representative of the wider population; however, focused research into non-hospital birth is unsurprising, as this type of decision-making is more ‘visible’ as a process because it is not normative. The ‘medical event’ ideology remains the authoritative narrative of pregnancy and birth, evidenced by women seeking care outside of the norm still rely on biomedical sanctions to do so, and by the fact that many births in Western countries take place in hospital settings.

This review further highlights the importance of the body in maternal health. Embodiment underpins women’s pregnancies and births [19], reflecting the liminality of these events, even if it is
not explicitly discussed. Embodied experiences are central to maternity, evidenced by the importance
mothers place on bodily autonomy and integrity, and how indicative emotions are within this.
Anthropologists have suggested that emotions affect how the body is experienced, and are connected
to images of well or poorly functioning social bodies.[72] Good motherhood continues to be heavily
associated with concepts of the appropriate maternal body. Research has previously suggested that a
fit, pregnant (or post-pregnancy) body is idealised and celebrated, and thus can be seen as a mark of
responsible, good motherhood. We would extend this further to include a good maternal body is one
that is *safe and informed* as well as fit. A maternal body out of control, uninformed or medically
unregulated induces uncertainty, anxiety, judgement and, to a certain extent, distrust, and this, in
turn, shapes decision-making about care. The inter-linking actions highlighted in our review may shift
emotional and ideological views of pregnancy and birth, and help individuals to calibrate care options
to themselves, their families and their environment. These considerations, strategies and actions are
all mediated *through* the maternal body, meaning that they should be considered as *embodied*.

Thus, an informed choice in a maternity care context is one that takes into account all the
information gathered and is aligned with a woman’s birth philosophy, the aspects of which have been
balanced against those of the other options. However, it is moderated by desires to maintain bodily
autonomy and integrity, discourses of uncertainty and motherhood performativity, framed temporally
and embedded in emotional and spatial considerations. From the research reviewed, it can be hard to
pin down to what extent women regularly make informed choices about their care; however, the
instances of it are relatively clear when they are articulated, and this is often by women who choose
home or free birth. They appear more likely to consider multiple options, opting for those that are
depth connected to their values and their bodies, and research extensively. This may be indicative of
medical systems constructed to support one pathway of care, but there is no reason a woman
receiving pregnancy care and giving birth in a more normalised settings should not be facilitated to
have similar decision-making experiences. In researching women who choose hospital or more
medicalised care, their relationships with choice are key to unpacking whether or not their choices
are informed, according to public health policy. Our conceptualisation of informed choice is one of many put forward since it became a buzzword in public health, yet it remains the case that, given the persistent power imbalances in biomedicine, it will continue to be defined by policymakers and HCPs. It may, in fact, be that women “are exposed to frameworks of choice rather than being explicitly able to formulate their own choices”. [73 p414] If this is the case, then researchers need to interrogate the possibilities for making informed choices in such a framework.

Limitations and further research

The meta-synthesis procedure provides an excellent guide for making sense of qualitative literature and concepts, but it may require a balancing act of what to include and what to exclude, revealing the inherent subjectivity of qualitative methodologies and the importance of reflexivity and transparency concerning how and why choices were made. Our meta-synthesis reviewed 37 sources, which, by some standards, may be considered too large and, therefore, a limitation. There are no strict recommendations on the size of a review; however, researchers should be aware that the framework may be better suited for smaller reviews, given the analysis and synthesis stages. We did consider curtailing the focus of this review to decision-making and informed choice about place of birth, but, ultimately, we felt that our analysis and discussion would benefit from a wider scope, as the findings would be useful for a broader audience in maternal health research.

In conducting this review, we identified three areas for further research. First, more research is needed on decision-making and informed choice among fathers and non-pregnant partners, as there is currently very little. Existing studies suggest that partners feel disembodied from pregnancy and vulnerable during labour and birth [74,75], and that they do take active roles in defending women’s choices and preparing for birth [76], showing the need for the development of an evidence base to enhance support and inclusion. Second, future research should prioritise generating findings from a wider European context, which would provide a better picture of women’s experiences in
these countries and how they are linked to the health care systems. Much of the research reviewed was based in the UK or USA, and the few studies from Denmark, Finland and Spain provided fresh insights into the national maternity services and decision-making realities within them. Finally, given the limited acknowledgement of the body in the studies reviewed and the dearth of qualitative research on maternal health incorporating theories of embodiment in general [77], future studies on decision-making and informed choice in these contexts should consider this dimension as a key theoretical starting point.

**Implications for policy and practice**

Our review demonstrates the need for a reconceptualisation of decision-making and informed choice as it concerns maternity care. Attempting to bridge policy and practice gaps through choice is common in maternity care, but there is often limited reflection on our own assumptions about the fundamental nature of making one, or what constitutes *informed* choice. Historically, women’s choices have been constrained, particularly concerning their livelihoods, and we should be mindful of how gender and hierarchy are iterated by contemporary frameworks of choice, such as through the performance of good motherhood. There is little consideration of the embodied dimensions of pregnancy, birth and decision-making experiences in classical theories of choice, or cyclical notions of temporality in current decision-making models, such as SDM. Reid et al [17] similarly found the framework for women’s decision-making processes about antenatal screening generated from their meta-synthesis was not fully congruent with existing theoretical frameworks. Our synthesis highlights informed choice as layered within a multidimensional process of decision-making, which may not be straightforwardly achieved through enshrinement in policy alone.

Our findings indicate that health systems should more actively incorporate flexibility and fluidity into practice, which was highlighted by several of the studies reviewed, but this may conflict with rigid structures for care. Maternal health experiences are highly personal, and there is need for
care systems that are flexible enough to accommodate them. However, hospital care has been
compared to an industrial factory, in which labour care resembles an assembly line [78,79], and
further research suggests that funnelling through specific care is still occurring.[80-82] Inflexible
information provision and care pathways may account for why women continue to rely on social and
familial networks and different media for support. They provide opportunities to acquire key
maternity knowledge but also leave space for personalisation, in that women are free to engage with
information when and as they choose. Decisions about care do not always take place at fixed points in
time, and this must be considered within any maternity choice framework.

In thinking of solutions, it is more important than ever to embrace emergent models in
maternity, like midwifery-led care, continuity of carer or group antenatal care [83], which support
more fluid decision-making, break down dichotomies and facilitate the social network effect.[84,85]
However, given the slow development of these models in health systems and comparatively low
uptake of ‘alternative’ options among women, even in countries with strong policy and midwifery
integration [86], there is still significant work to be done on normalising these pathways. HCPs, given
their trusted expertise, hold a unique position, allowing them to spearhead change in maternity care,
beginning by shifting narratives of safety and risk. Women are often concerned with uncertainty in
pregnancy, labour and birth when making a decision, so effectively and transparently communicating
about risk and safety in different care settings will be crucial in promoting and legitimising emergent
models. Placing more trust and respect, especially trusting women’s experiences and respecting their
bodily autonomy and integrity, in care giving and receiving will also help to make strides in
restructuring not only the services, but the way we think about relationships within them.

Conclusions

This is the first systematic review to take a wider maternity context into consideration in order to
elucidate decision-making and informed choice about pregnancy and birth care. Building on the
critical reinterpretation of the included studies, we developed a conceptual synthesis, which was consistent with the findings of these but also extended beyond them. Most of the studies reviewed here were of moderate to high quality, and there has been an increasing focus on decision-making and informed choice, particularly in regards to place of birth, in the literature since the 2010s, a trend that is likely to continue, as choice remains prominent in public health policymaking. In light of this review, we urge researchers, practitioners and policymakers to take the embodied experience of pregnancy and birth and dynamic processes of decision-making into account when forming care pathways and tackling informed choice therein.

* Denotes results from the second search conducted in August 2019.
January 2017 search

Identification
- 1646 records identified through database searches

Screening
- 1139 records screened by title/abstract
- 69 selected for full text screening

August 2019 search

Identification
- 552 records identified through database searches
- 655 duplications removed

Screening
- 404 records screened by title/abstract
- 1455 did not meet the inclusion criteria
- 19 selected for full text screening
- 1 article known to the authors added in for full text review
- 47 excluded from the review
  - 33 main focus was not on experiences of decision-making
  - 9 methodology or data reported were not part of inclusion criteria
  - 3 decision-making during labour
  - 1 decision-making about pregnancy termination
  - 1 published before 1990

Quality appraisal
- 35 included in quality appraisal
- 7 included in quality appraisal
- 5 were excluded due to low quality

37 (36 articles, 1 thesis) included in the review
